## Theorems and Formulae

**Montmort Numbers** count the number of derangements (permutations where no element appears in its original position) of a set of size  $n$ .  $!0 = 1$ ,  $!1 = 0$ ,  $!n = (n+1)(!(n-1)+!(n-2))$ ,  $!n = n! \sum_{i=0}^n \frac{(-1)^i}{i!}$ ,  $!n = \lfloor \frac{n!}{e} \rfloor$

In a partially ordered set, a chain is a subset of elements that are all comparable to each other. An antichain is a subset where no two are comparable.

**Dilworth's theorem** states the size of a maximal antichain equals the size of a minimal chain cover of a partially ordered set  $S$ . The width of  $S$  is the maximum size of an antichain in  $S$ , which is equal to the minimum number of chains needed to cover  $S$ , or the minimum number of chains such that all elements are in at least one chain.

**Rosser's Theorem** states the  $n$ th prime number is greater than  $n * \ln(n)$  for  $n > 1$ .

**Nicomachi's Theorem** states  $1^3 + 2^3 + \dots + n^3 = (1 + 2 + \dots + n)^2$  and is equivalent to  $(n \frac{n+1}{2})^2$ .

**Lagrange's Four Square Theorem** states every natural number is the sum of the squares of four non-negative integers. This is a special case of the **Fermat Polygonal Number Theorem** where every positive integer is a sum of at most  $n$   $s$ -gonal numbers. The  $n$ th

$s$ -gonal number  $P(s, n) = (s-2) \frac{n(n-1)}{2} + n$
