Theorems and Formulae

Montmort Numbers count the number of derangements (permutations where no element appears in its original position) of a set of size n. !0 = 1, !1 = 0, !n = (n+1)(!(n-1))1)+!(n-2)), ! $n = n! \sum_{i=0}^{n} \frac{(-1)^i}{i!}$, ! $n = \left[\frac{n!}{e}\right]$ In a partially ordered set, a chain is a subset of elements that are all comparable to each other. An antichain is a subset where no two are combarable.

Dilworth's theorem states the size of a max-□ imal antichain equals the size of a minimal chain cover of a partially ordered set S. The width of S is the maximum size of an antichain in S, which is equal to the minimum number of chains needed to cover S, or the minimum number of chains such that all elements are in return circuit.size()-1==edges.size(); at least one chain.

Rosser's Theorem states the nth prime number is greater than n * ln(n) for n > 1.

[Nicomachi's Theorem states $1^3 + 2^3 + ... + \frac{\text{define FOR}(i,n)}{\text{for (int } i = 0; i < n; i++)}$] and is equivalent to void floydWarshall (Vec<2, 11>& m) { $(n^{\frac{n+1}{2}})^2$.

Lagrange's Four Square Theorem states & && m[k][j] != inf) { every natural number is the sum of the squares auto newDist = max(m[i][k] + m[k][j], -inf); of four non-negative integers. This is a special case of the Fermat Polygonal Number FOR(k,n) if (m[k][k] < 0) FOR(i,n) FOR(j,n) Theorem where every positive integer is a if (m[i][k] != inf && m[k][j] != inf) **Theorem** where every positive integer is a sum of at most n s-gonal numbers. The nths-gonal number $P(s, n) = (s - 2)\frac{n(n-1)}{2} + n$
